Microbes and flow cytometry:

from enumeration to community structure, diversity and ecosystem function

Josep M Gasol

Departament de Biologia Marina, Institut de Ciències del Mar. CSIC. Barcelona

Our ultimate goal

Dalibacter banyuleus

preferentially grazed by HNF

very sensitive to viral attack

Spirovibrio kalmariensis

Roundicoccus plymouthii

In summer, 75% of BCD

dominates DMSP uptake

Tinymonas bremenensis

(all names are fiction… yet)

Microbes and flow cytometry (bias to heterotrophs)

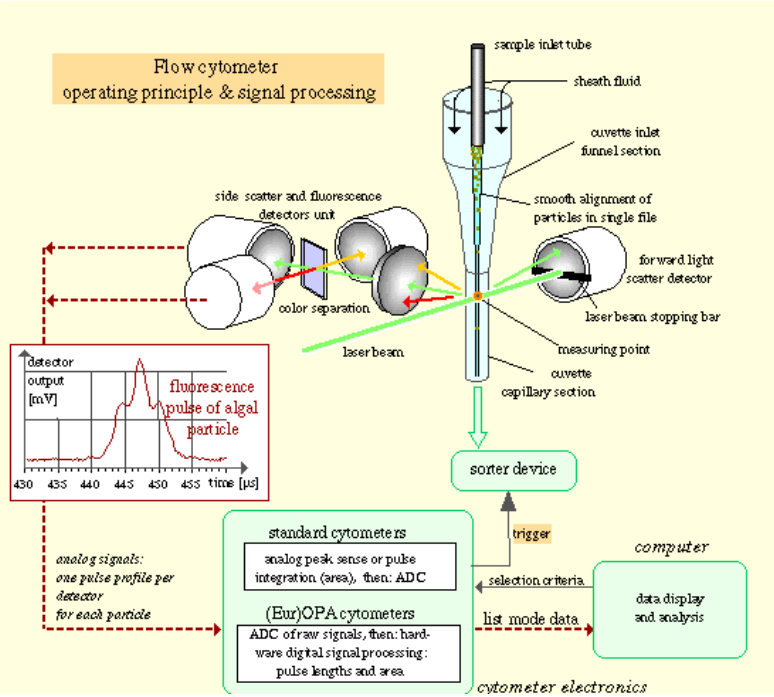
1) Introduction: what is CF?
2) Cellular size and structure, and pigment detection
3) Detecting bacterial, viral and protistal DNA (and RNA)
4) Measuring Bacterial activity and physiological status
5) Where are we? A personal view of our achievements (and lack of)
6) Going further: cytometric diversity
7) Going further: Probing ecosystem function
   Relating community structure to ecosystem functioning

Microbes and flow cytometry (bias to heterotrophs)

1) Introduction: what is CF?
2) Cellular size and structure, and pigment detection
3) Detecting bacterial, viral and protistal DNA (and RNA)
4) Measuring Bacterial activity and physiological status
5) Where are we? A personal view of our achievements (and lack of)
6) Going further: cytometric diversity
7) Going further: Probing ecosystem function
   Relating community structure to ecosystem functioning

Flow Cytometry

- Measurement of individual cells
  (a fluidics system forces them to pass one at a time)
- It can measure:
  - Scattered light
    - FSC (FALS): light scattered at angles < 10°
    - SSC (RALS): light scattered at 90°
  - Fluorescence
    - after excitation by 350 nm (UV), 488 nm (Blue), 630 (red)...
- Up to 7/8 parameters in thousands of cells per second
- Enumeration /community structure / sorting
- Advantages
  - (Many) Individual cells
  - Better statistics
  - Supopulations can be identified
  - Cells can be sorted
- Disadvantages
  - Cells must be isolated
  - Limited information on structure
  - < 70 µm
  - ≤ 800 particles ml^{-1}



- High-speed cell sorters
  - Coulter EPICS, FACSVantage
  - FACSAria - MoFlo - Influx
- Medium-size cytometers
  - FacsCalibur, Coulter XL
  - FACSCanto, FACSVerse
- Portable cytometers
  - Guava, Apogee, Partec, Miltenyi
  - Accuri
- In situ - continuously monitoring FC
  - FlowCytobuoy, Flowcytobot
  - SeaFlow

- High-speed cell sorters
  Coulter EPICS, FACSVantage
  FACSAria - MoFlo - Influx

Thanks google for the images...

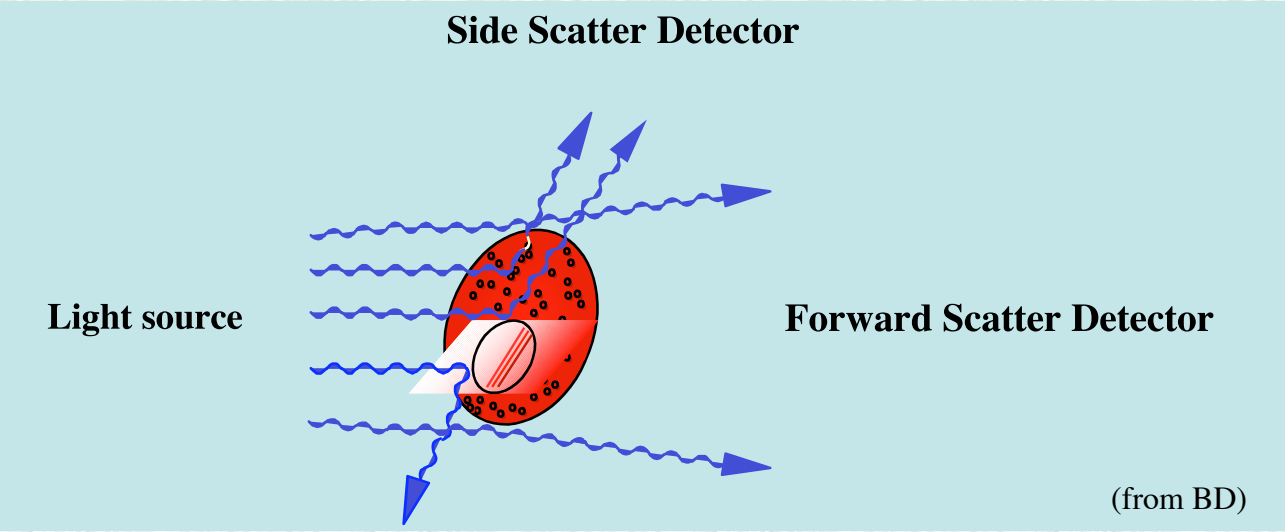
Flow Cytometry-1

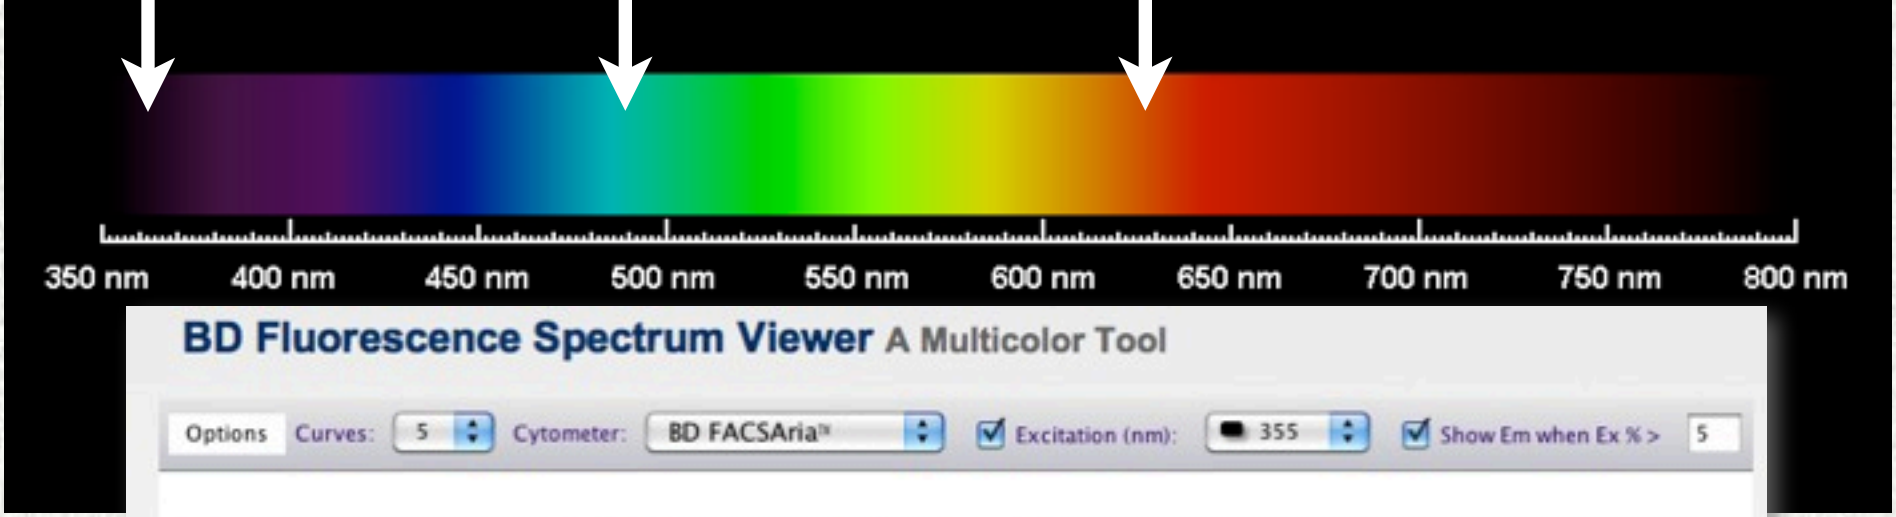
- Cytometry = Cyto (=cell) Metry (=measurement)
- Light scattered in two angles



images from BD

- Fluorescence: A fluorophore (fluorescent molecule) has the property of absorbing light energy (excitation) and to restore it quickly (< 1 ns) as fluorescent light (emission). The wavelength of the emission must be longer (less energetic) than that of the excitation light (this is called the Stoke's law)

- Characteristics of fluorochromes: affinity for target, excitation and emmision peaks, extinction coefficient, and photobleaching.



BD Fluorescence Spectrum Viewer A Multicolor Tool

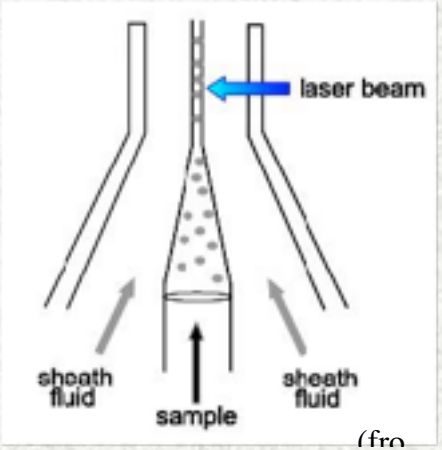
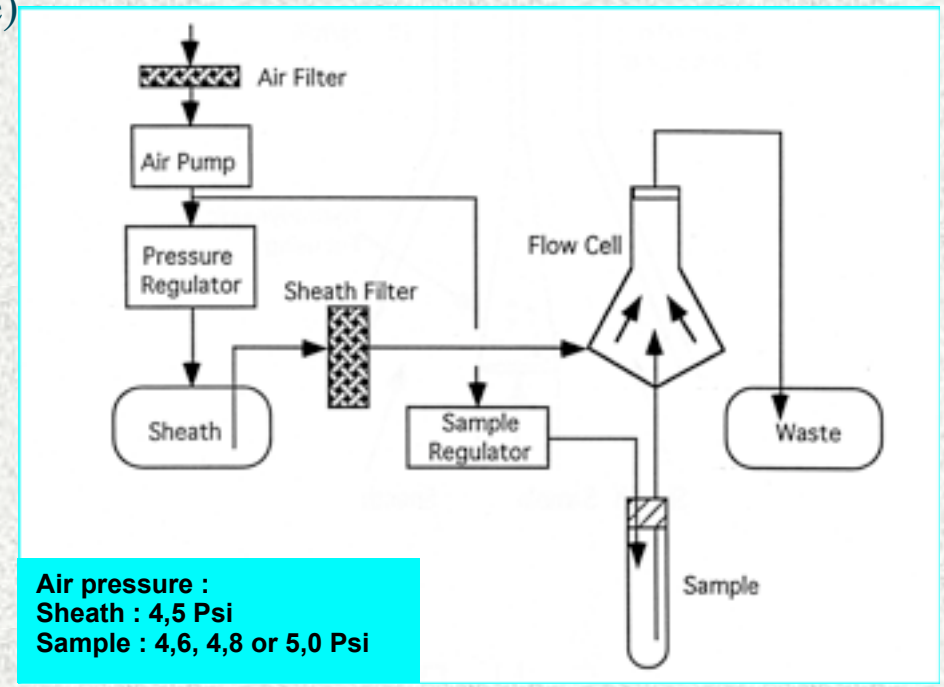
Flow Cytometry-2

- FC is based on three/four elements:
  - *Fluidics*: introduction and positioning of the cells
  - *Optics*: production of the signal and collection on PMT
  - *Electronics*: transformation of the photon signals into electronic signals proportional to the intensity of the light. Amplification and digitalization of signals
  - *Sorting*: After-processing cell separation

- FLUIDICS
- differential pressure (regulates flow rate)
- laminar flow
- hydrodynamic focusing
- sheath fluid





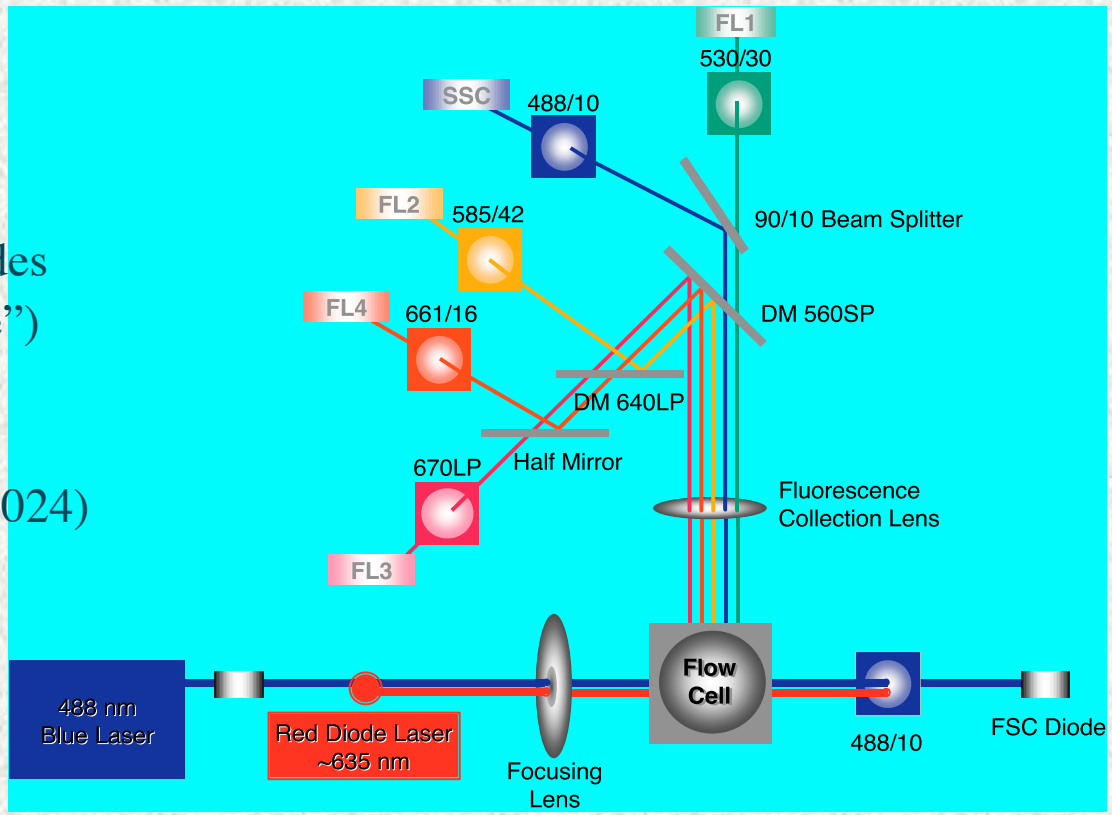
Air pressure :
Sheath : 4,5 Psi
Sample : 4,6, 4,8 or 5,0 Psi

images from BD

Flow Cytometry-3

- OPTICS
- laser(s): Argon, He-Ne, He-Cd, Kr // LEDs // Arc-Lamp (Mercury-Xenon)
  Typically, UV (355 nm), Blue (488 nm), Red (655 nm)
- filters: Longpass / Bandpass / Shortpass
- lenses/prisms/dichroic mirrors.

- ELECTRONICS
- photomultipliers or photodiodes
- signal amplification ("voltage")
- signal thresholding
- signal processing
- classification into channels (1024)
- computer-based processing



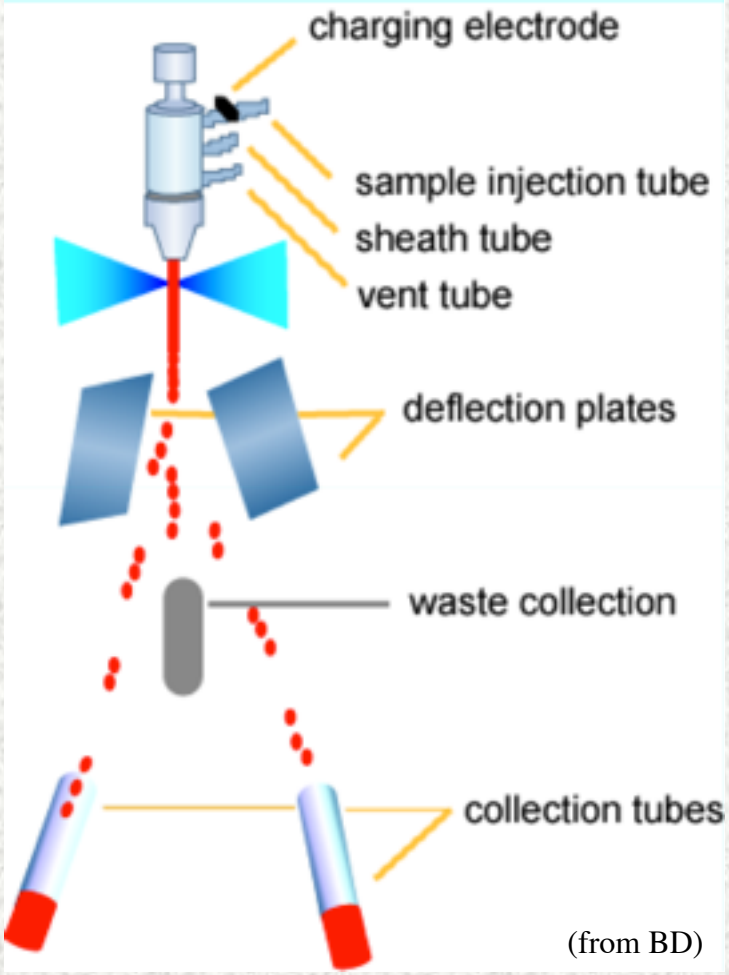
images from BD

Flow Cytometry-4

- SORTING

- Mechanical (in a flow cell) or electrostatic ("stream in air")
- stream in air: a vibrating nozzle creates spaced droplets which are then electrically charged

Mechanical	Electrostatical
Low Speed (300 s^{-1})	High-speed (>10000 s^{-1})
Flow cell	Stream in air (nozzle)
Laser fixed and aligned	Needs laser alignement
Mehanical sort	Electrostatic sort
Shaeth can vary	Saline sheath
Sort in one way	Sort in two ways
No aerosol	Creates aerosols
Highly-diluted sort	(almost) Undiluted sorting
Choice for radioact samples	Choice for molec. studies

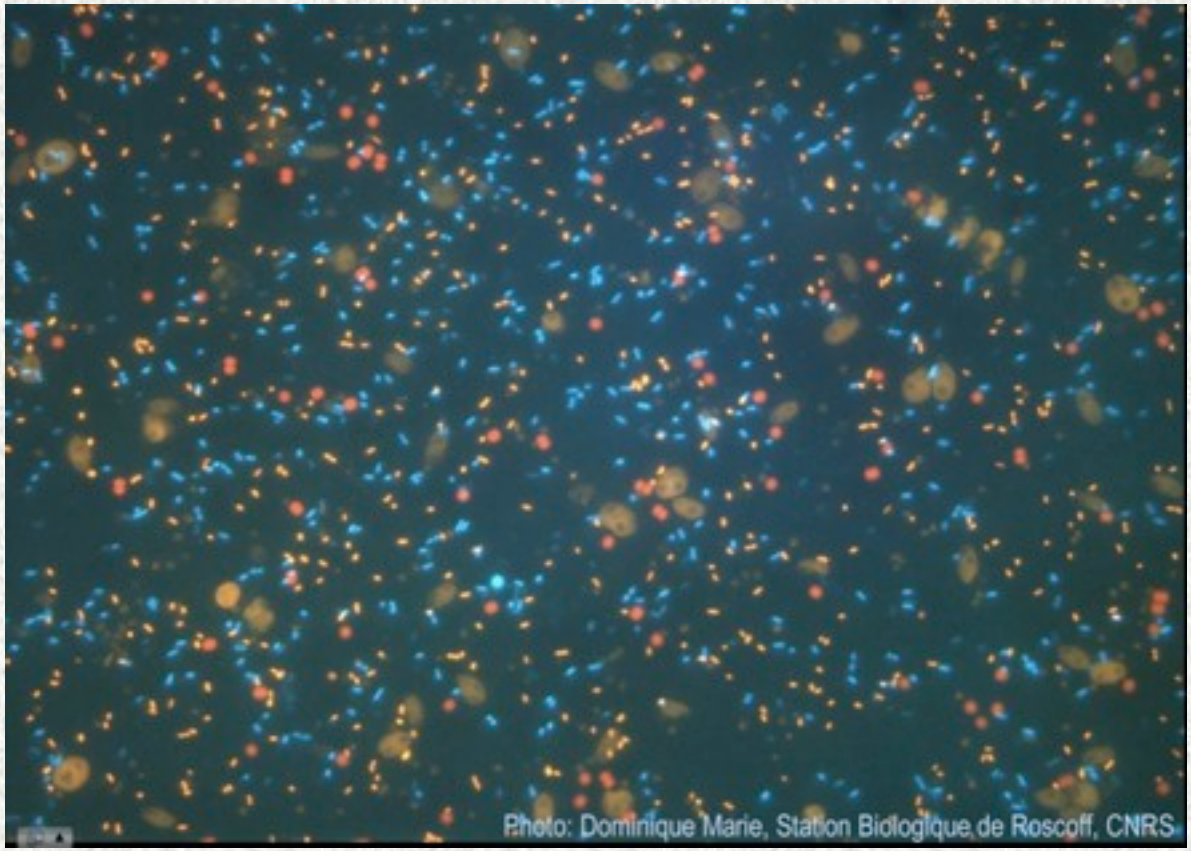


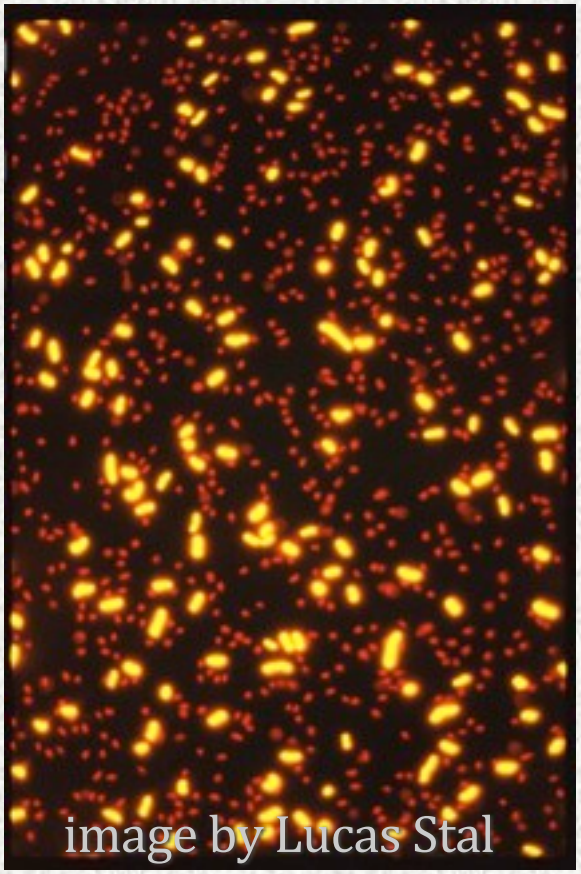
Microbes and flow cytometry (bias to heterotrophs)

1) Introduction: what is CF?
2) Cellular size and structure, and pigment detection
3) Detecting bacterial, viral and protistal DNA (and RNA)
4) Measuring Bacterial activity and physiological status
5) Where are we? A personal view of our achievements (and lack of)
6) Going further: cytometric diversity
7) Going further: Probing ecosystem function
   Relating community structure to ecosystem functioning

Size and (auto)fluorescence

- Autofluorescence: natural emission of light by certain molecules after they have absorbed (excitation) light
- CHL, BCHLs, Phycobilins (Phycocyanin, phycoeritrin, allophycocyanine) have autofluorescence
- Carotenoids do not have it. SO not all pigments have fluorescence.





Size and (auto)fluorescence

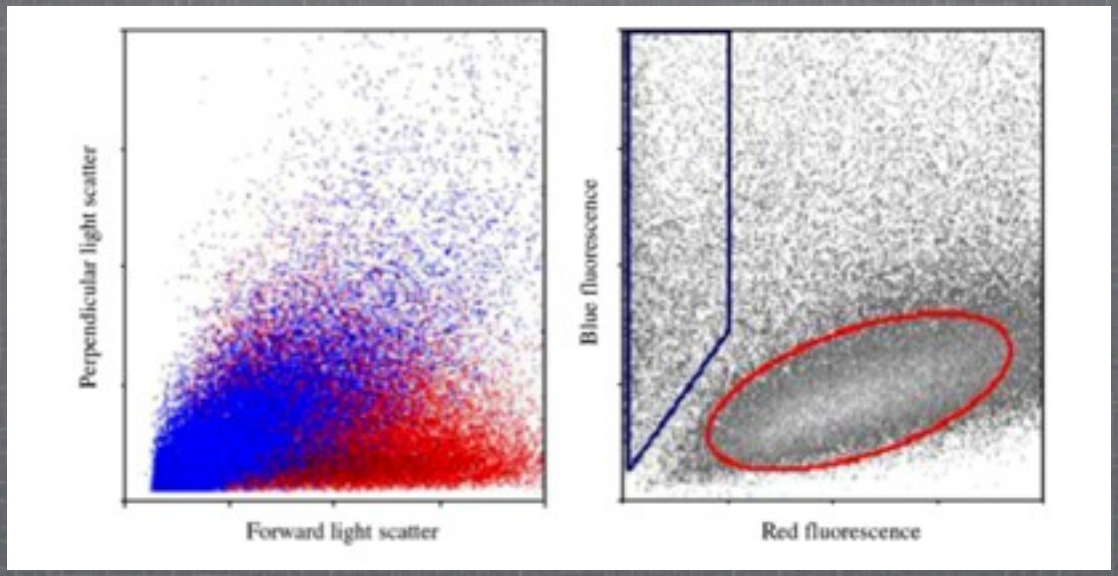
Marine microgels: Optical and proteomic fingerprints

Mónica V. Orellana [a,*], Timothy W. Petersen [a,1], Alan H. Diercks [a], Samuel Donohoe [a,2], Pedro Verdugo [b], Ger van den Engh [a,1,3]



Dissolved organic matter (DOM) is a major carbon reservoir for the global carbon cycle, and its molecules play a key role in the biogeochemistry of the ocean. Colloidal DOM macromolecules assemble to form polymer hydrogels known as marine microgels. Marine microgels represent one of the most dynamic pools of organic carbon in the ocean. However, their optical characteristics and their contribution to ocean optical properties are largely unknown. In this work, we explore the optical and proteomic properties of spontaneously assembled DOM polymer microgels. Microgels from cultures and from Puget Sound seawater were sorted and counted using a dual-laser (365 nm/365 nm) high-speed cell sorter. This sorter has been adapted to interface with a scanning monochromator to measure the fluorescence emission spectrum of the microgels over the range from 300 to 850 nm. Surprisingly, the microgels show a broad fluorescence emission from 420 to 520 nm when excited with UV light. The microgels were classified according to their blue autofluorescence, and by three criteria that are used to define microgels: 1) staining with chlortetracycline 2) the ability to undergo phase transitions at low pH, and 3) dispersion following calcium chelation by EDTA.

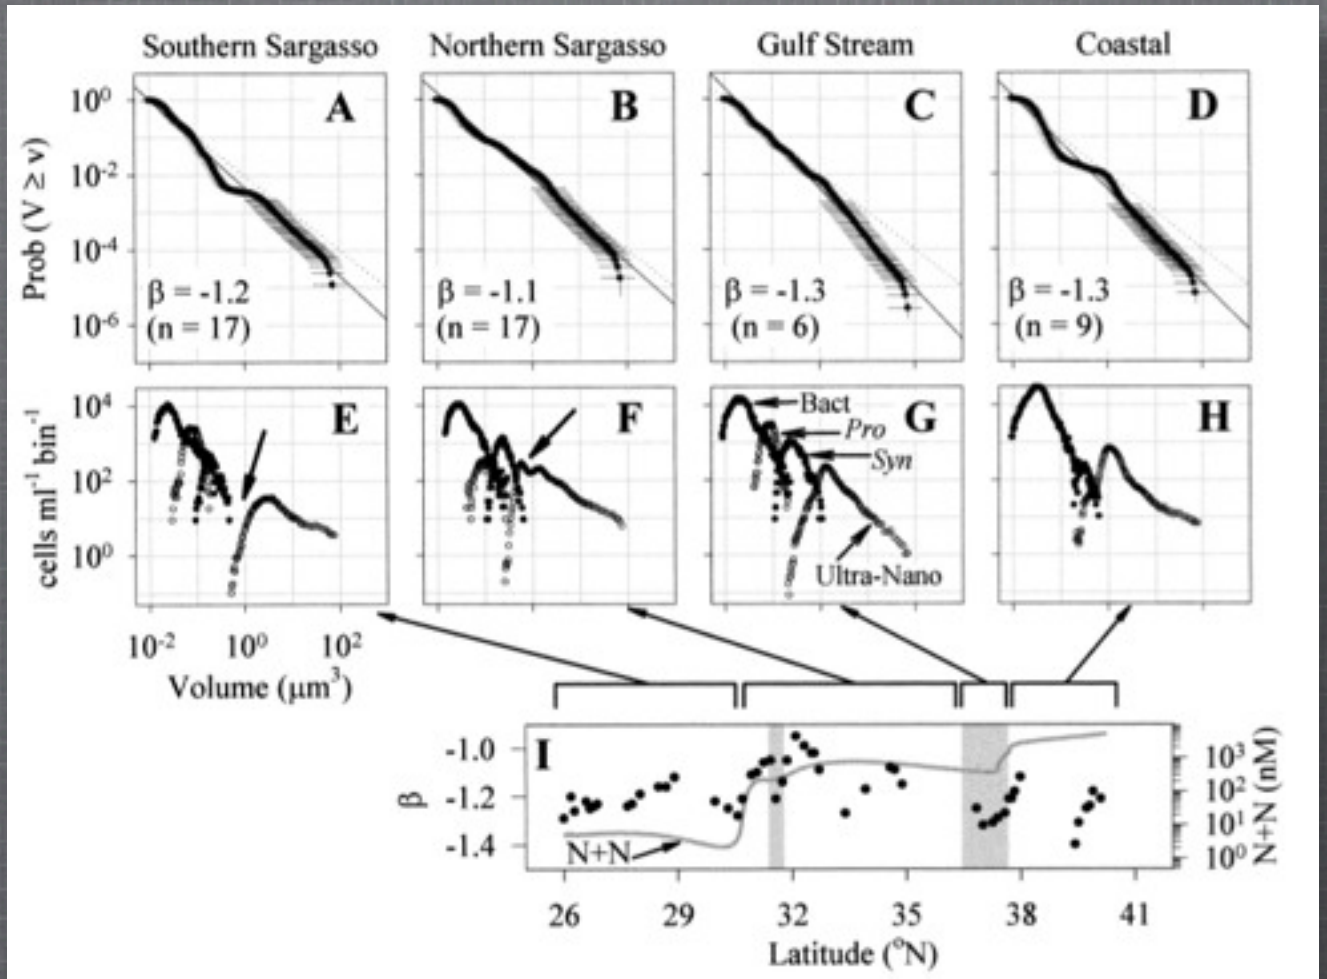
  - inorganic particles (Saharan dust, black carbon)
  - particle-attached microbes
- Many physiological probes been tried (for live/dead - active/inactive)
- Not yet: good understanding of "microbial death" and physiological community structure
- Relate scatter and cell size and build phytoplankton Size spectra



Cavender-Bares et al. 2001-L&O

A personal view of the last 20 yr. highlights

- Routine enumeration of pico- and nanoalgae (>80's)
- Not yet: enumeration of large and "rare" cells
- Routine enumeration of heterotrophic bacteria (90's)
- Routine enumeration of planktonic viruses (00's)
- Enumeration of heterotrophic protists (05's)
- Not yet: enumeration of BChlorophyll containing microorganisms
- Not yet: non-living particles, and particle-attached microbes
  - organic particles (gels...)
  - inorganic particles (Saharan dust, black carbon)
  - particle-attached microbes
- Many physiological probes been tried (for live/dead - active/inactive)
- Not yet: good understanding of "microbial death" and physiological community structure
- Relate scatter and cell size and build phytoplankton Size spectra
- Not yet: Build bacterioplankton size spectra

Microbes and flow cytometry (bias to heterotrophs)

Cytometric diversity in marine ultraphytoplankton

W. K. W. Li
Biological Oceanography Section, Bedford Institute of Oceanography, P.O. Box 1006, Dartmouth, Nova Scotia B2Y 4A2

Abstract

The concept and methods of ecological diversity in communities were applied to phytoplankton categorized by flow cytometric measurements related to size and chlorophyll content. Each cytometric signature was condensed to single numerical values indicative of diversity and evenness. Measurements pooled from studies disparate in temporal and spatial scales indicated greater chlorophyll biomass and primary production with greater cytometric diversity and evenness. Future development of these ideas may help link biological oceanographic processes with patterns established through ecological processes at the community level.

4.4. Diversity patterns

As can be seen in Table 3, the number of classes of the different variables considered (S_x) tended to decrease with salinity and reached the minimal values in the crystallizers. All S_x indices were significantly correlated (Table 4). Due to the variety of methods used, different numbers of classes must be expected, even when dealing with the same organisms. For example, morphological differences among filamentous cyanobacteria, will not

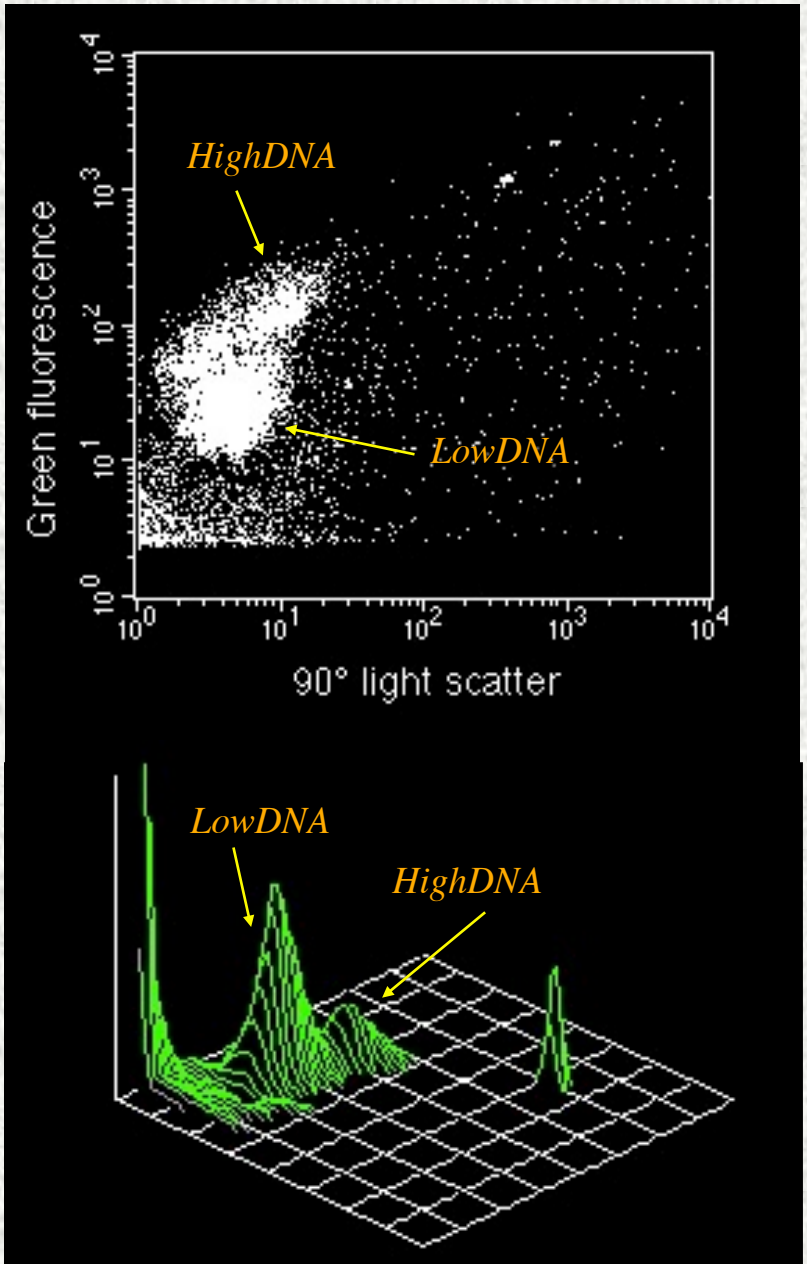
An example of cell sorting and diversity

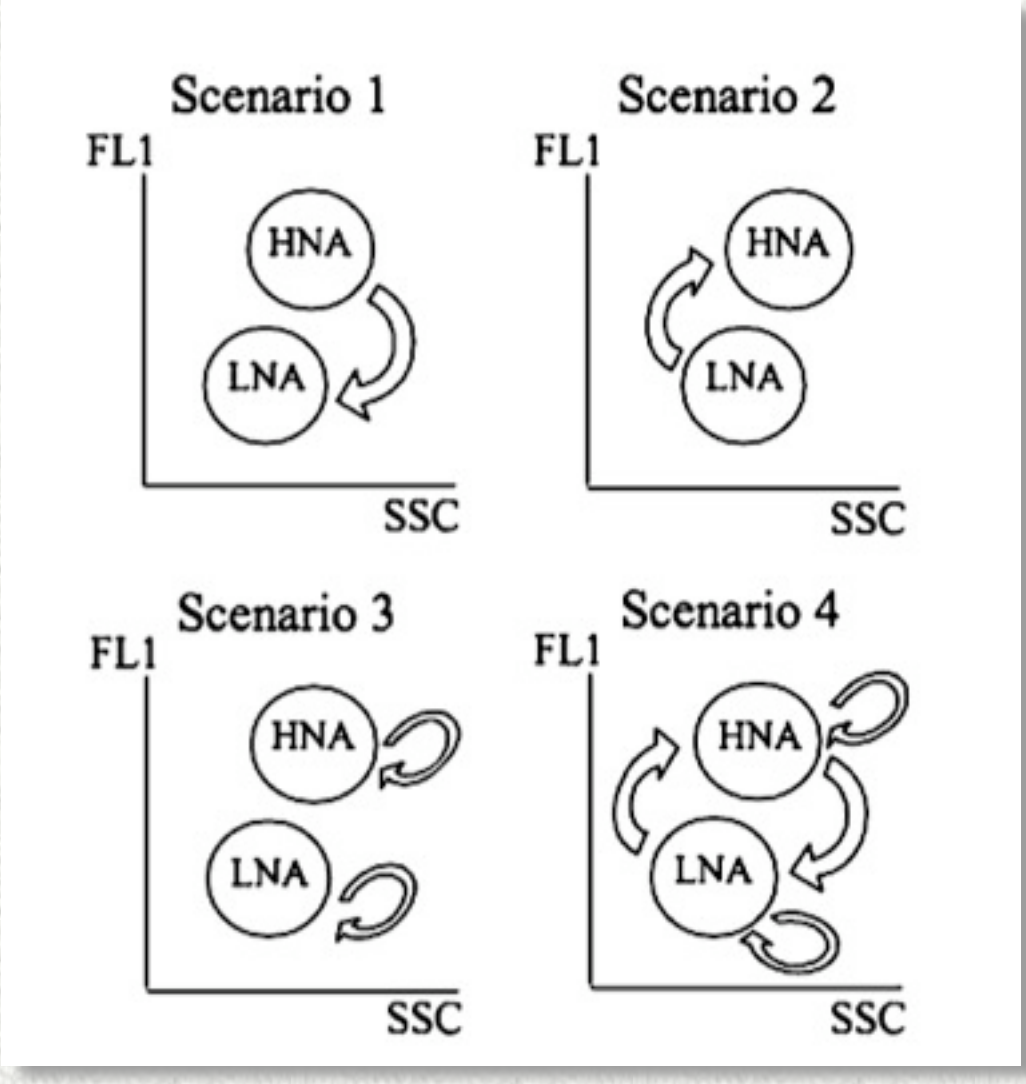
- Bacteria can be detected by flow cytometry after DNA staining

- It works similarly well with most DNA stains (Syto9, SybrGreen...)

- A plot of "size" (light scatter) vs. DNA fluorescence allows enumeration

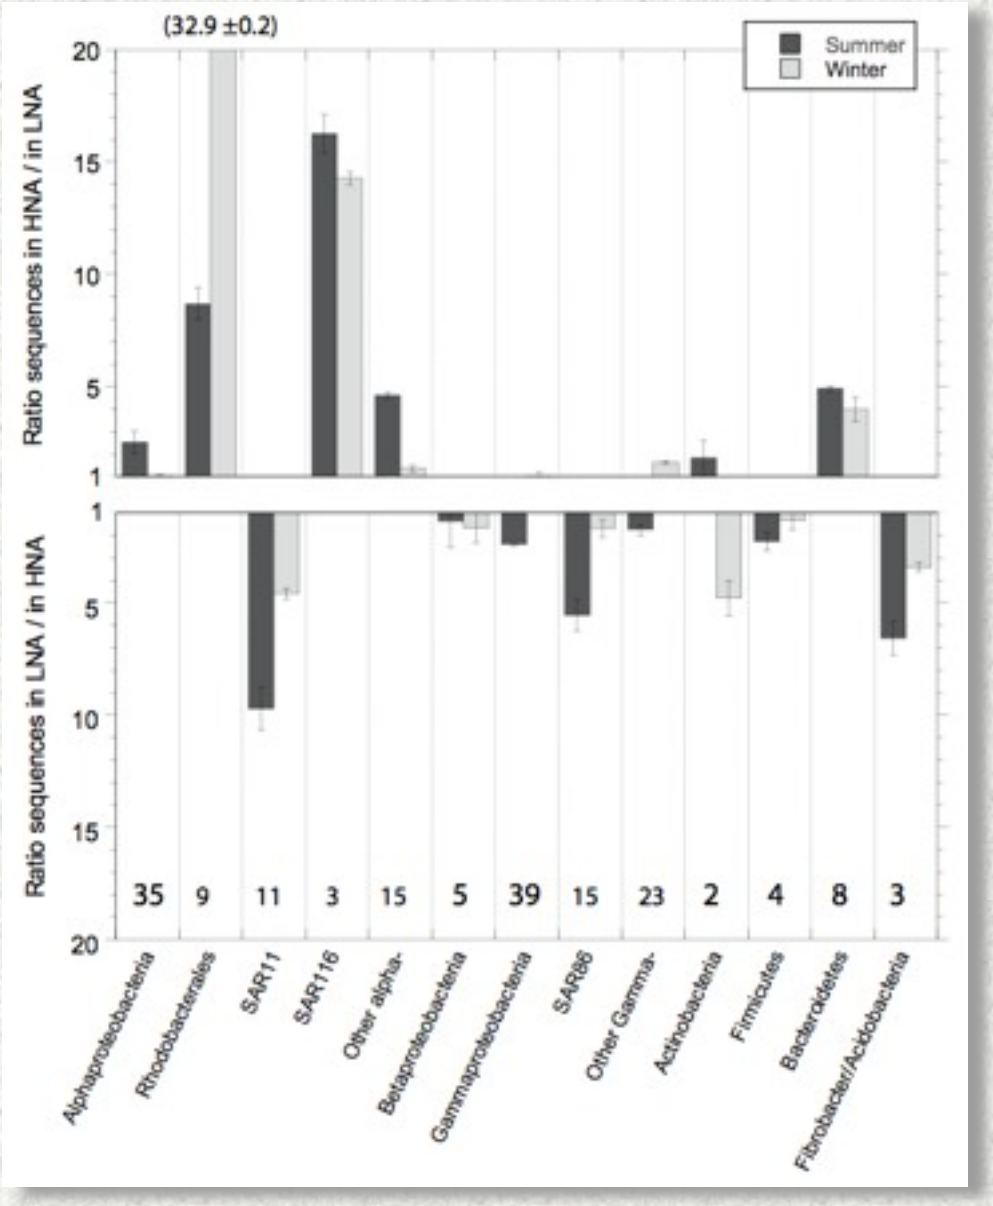
- Surprinsingly, at least two clear populations can be seen: HNA and LNA in almost all types of samples

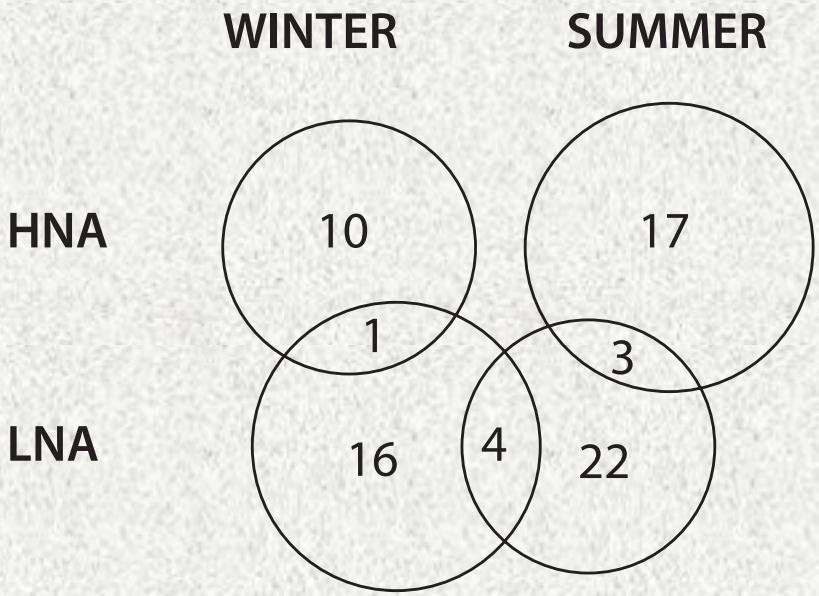




Bouvier et al'07-ENM

OK. Let's sort them out and deep sequence the populations
How many (OTUs) are common to the HNA and LNA?





Abundant (>1% sequences) OTUs
